#### **Decision Trees**

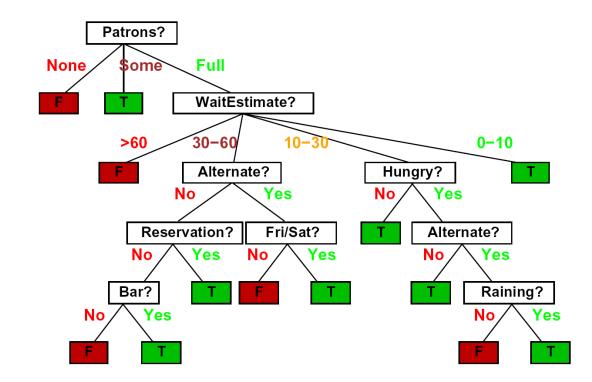

#### **Reminder: Features**

- Features, aka attributes
  - Sometimes: TYPE=French
  - Sometimes:  $f_{\text{TYPE=French}}(x) = 1$

Example		Attributes									Target
	Alt	Bar	Fri	Hun	Pat	Price	Rain	Res	Type	Est	WillWait
$X_1$	T	F	F	Т	Some	\$\$\$	F	T	French	0–10	Т
$X_2$	T	F	F	Т	Full	\$	F	F	Thai	30–60	F
$X_3$	F	Т	F	F	Some	\$	F	F	Burger	0–10	Т
$X_4$	T	F	Т	Т	Full	\$	F	F	Thai	10–30	Т
$X_5$	T	F	Т	F	Full	\$\$\$	F	T	French	>60	F
$X_6$	F	Т	F	Т	Some	\$\$	T	T	Italian	0–10	Т
$X_7$	F	Т	F	F	None	\$	<i>T</i>	F	Burger	0–10	F
$X_8$	F	F	F	Т	Some	\$\$	T	T	Thai	0–10	Т
$X_9$	F	Т	Т	F	Full	\$	<i>T</i>	F	Burger	>60	F
$X_{10}$	T	Т	Т	Т	Full	\$\$\$	F	T	Italian	10–30	F
$X_{11}$	F	F	F	F	None	\$	F	F	Thai	0–10	F
$X_{12}$	T	Т	Т	Т	Full	\$	F	F	Burger	30–60	Т

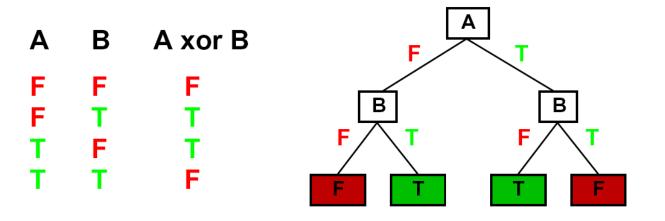

### **Decision Trees**

- Compact representation of a function:
  - Truth table
  - Conditional probability table
  - Regression values
- True function
  - Realizable: in *H*

### Expressiveness of DTs

Can express any function of the features

P(C|A, B)

However, we hope for compact trees

### **Comparison:** Perceptrons

What is the expressiveness of a perceptron over these features?

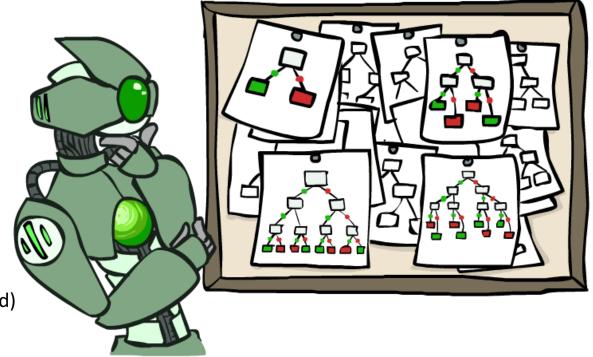

Example		Attributes										
	Alt	Bar	Fri	Hun	Pat	Price	Rain	Res	Type	Est	WillWait	
$X_1$	T	F	F	Т	Some	\$\$\$	F	Т	French	0–10	Т	
$X_2$	T	F	F	Т	Full	\$	F	F	Thai	30–60	F	

- For a perceptron, a feature's contribution is either positive or negative
  - If you want one feature's effect to depend on another, you have to add a new conjunction feature
  - E.g. adding "PATRONS=full WAIT = 60" allows a perceptron to model the interaction between the two atomic features
- DTs automatically conjoin features / attributes
  - Features can have different effects in different branches of the tree!
- Difference between modeling relative evidence weighting (NB) and complex evidence interaction (DTs)
  - Though if the interactions are too complex, may not find the DT greedily

## Hypothesis Spaces

#### How many distinct decision trees with n Boolean attributes?

- = number of Boolean functions over n attributes
- = number of distinct truth tables with 2<sup>n</sup> rows
- = 2^(2<sup>n</sup>)
- E.g., with 6 Boolean attributes, there are 18,446,744,073,709,551,616 trees
- How many trees of depth 1 (decision stumps)?
  - = number of Boolean functions over 1 attribute= number of truth tables with 2 rows, times n
  - = 4n
  - E.g. with 6 Boolean attributes, there are 24 decision stumps
- More expressive hypothesis space:
  - Increases chance that target function can be expressed (good)
  - Increases number of hypotheses consistent with training set (bad, why?)
  - Means we can get better predictions (lower bias)
  - But we may get worse predictions (higher variance)

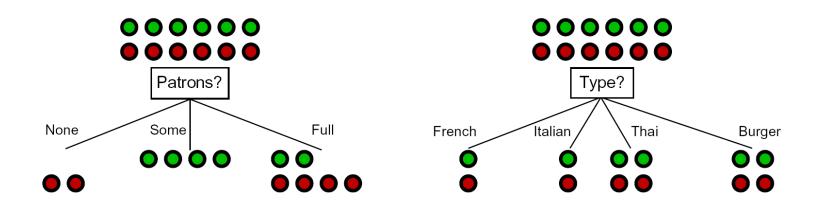

## **Decision Tree Learning**

- Aim: find a small tree consistent with the training examples
- Idea: (recursively) choose "most significant" attribute as root of (sub)tree

```
function DTL(examples, attributes, default) returns a decision tree
if examples is empty then return default
else if all examples have the same classification then return the classification
else if attributes is empty then return MODE(examples)
else
     best \leftarrow CHOOSE-ATTRIBUTE(attributes, examples)
     tree \leftarrow a new decision tree with root test best
     for each value v_i of best do
         examples_i \leftarrow \{ elements of examples with best = v_i \}
         subtree \leftarrow DTL(examples_i, attributes - best, MODE(examples))
         add a branch to tree with label v_i and subtree subtree
     return tree
```

## Choosing an Attribute

 Idea: a good attribute splits the examples into subsets that are (ideally) "all positive" or "all negative"

 So: we need a measure of how "good" a split is, even if the results aren't perfectly separated out

## **Entropy and Information**

#### Information answers questions

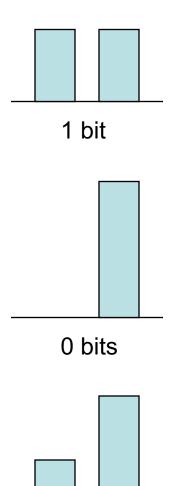

- The more uncertain about the answer initially, the more information in the answer
- Scale: bits
  - Answer to Boolean question with prior <1/2, 1/2>?
  - Answer to 4-way question with prior <1/4, 1/4, 1/4, 1/4>?
  - Answer to 4-way question with prior <0, 0, 0, 1>?
  - Answer to 3-way question with prior <1/2, 1/4, 1/4>?
- A probability p is typical of:
  - A uniform distribution of size 1/p
  - A code of length log 1/p

# Entropy

- General answer: if prior is  $\langle p_1, ..., p_n \rangle$ :
  - Information is the expected code length

$$H(\langle p_1, \dots, p_n \rangle) = E_p \log_2 1/p_i$$
$$= \sum_{i=1}^n -p_i \log_2 p_i$$

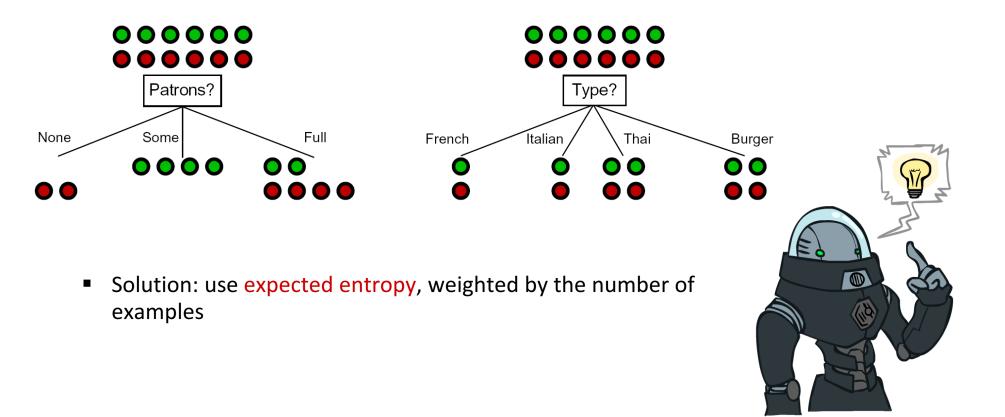

- Also called the entropy of the distribution
  - More uniform = higher entropy
  - More values = higher entropy
  - More peaked = lower entropy
  - Rare values almost "don't count"

## Information Gain

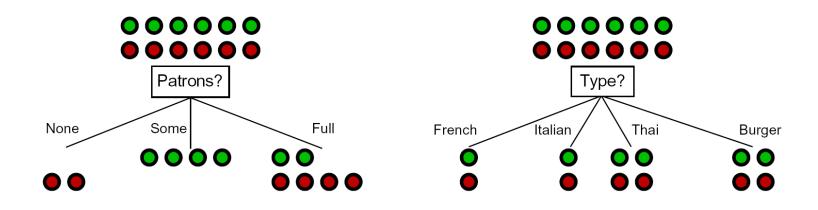

- Back to decision trees!
- For each split, compare entropy before and after
  - Difference is the information gain
  - Problem: there's more than one distribution after split!

## **Information Gain**

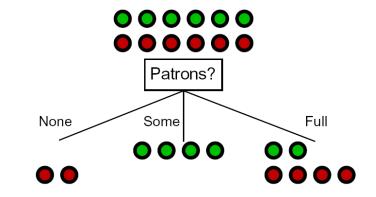

- Back to decision trees!
- For each split, compare entropy before and after
  - Difference is the information gain
  - Problem: there's more than one distribution after split!

- Solution: use expected entropy, weighted by the number of examples
- Note: hidden problem here! Gain needs to be adjusted for large-domain splits – why?

#### Next Step: Recurse

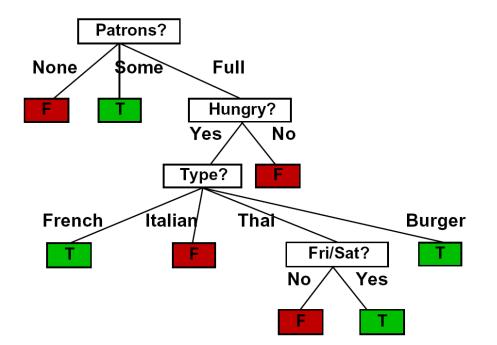

- Now we need to keep growing the tree!
- Two branches are done (why?)
- What to do under "full"?
  - See what examples are there...

Example	Attributes										Target
p	Alt	Bar	Fri	Hun	Pat	Price	Rain	Res	Type	Est	WillWait
$X_1$	Т	F	F	Т	Some	\$\$\$	F	T	French	0–10	Т
$X_2$	Т	F	F	Т	Full	\$	F	F	Thai	30–60	F
$X_3$	F	Т	F	F	Some	\$	F	F	Burger	0–10	Т
$X_4$	Т	F	Т	Т	Full	\$	F	F	Thai	10–30	Т
$X_5$	Т	F	Т	F	Full	\$\$\$	F	T	French	>60	F
$X_6$	F	Т	F	Т	Some	\$\$	Т	T	Italian	0–10	Т
$X_7$	F	Т	F	F	None	\$	Т	F	Burger	0–10	F
$X_8$	F	F	F	Т	Some	\$\$	Т	T	Thai	0–10	Т
$X_9$	F	Т	Т	F	Full	\$	Т	F	Burger	>60	F
$X_{10}$	Т	Т	Т	Т	Full	\$\$\$	F	Т	Italian	10–30	F
$X_{11}$	F	F	F	F	None	\$	F	F	Thai	0–10	F
$X_{12}$	Т	Т	Т	Т	Full	\$	F	F	Burger	30–60	Т

### Example: Learned Tree

Decision tree learned from these 12 examples:

- Substantially simpler than "true" tree
  - A more complex hypothesis isn't justified by data
- Also: it's reasonable, but wrong

#### Example: Miles Per Gallon

mpg	cylinders	displacement	horsepower	weight	acceleration	modelyear	maker
						751 70	
good		low	low	low	high	75to78	asia
bad	6	medium	medium	medium	medium	70to74	america
bad	4	medium	medium	medium	low	75to78	europe
bad	8	high	high	high	low	70to74	america
bad	6	medium	medium	medium	medium	70to74	america
bad	4	low	medium	low	medium	70to74	asia
bad	4	low	medium	low	low	70to74	asia
bad	8	high	high	high	low	75to78	america
:	:	:	:	:	:	:	:

good	4	medium	low	low	low	79to83	america
good	4	low	low	medium	high	79to83	america
bad	8	high	high	high	low	70to74	america
good	4	low	medium	low	medium	75to78	europe
bad	5	medium	medium	medium	medium	75to78	europe

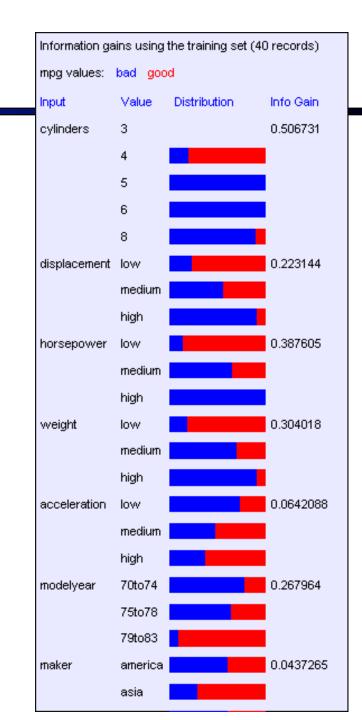

40 Examples

# Find the First Split

 Look at information gain for each attribute

Note that each attribute is correlated with the target!

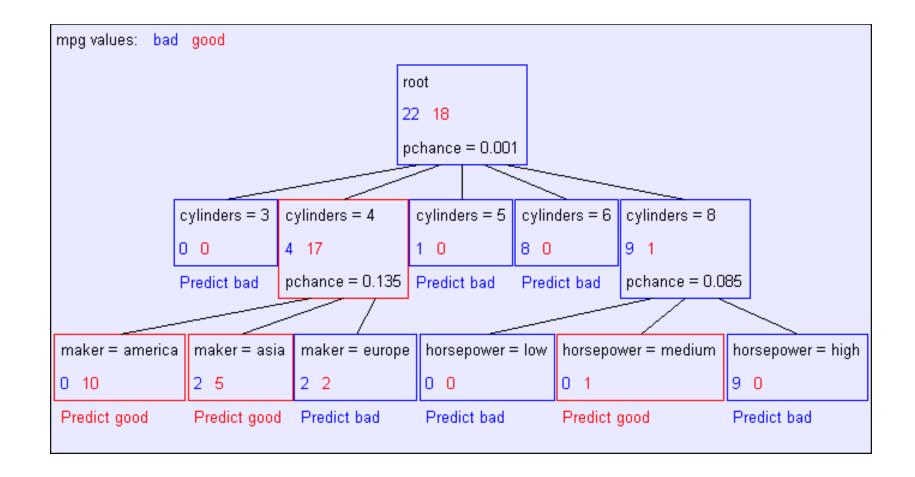

What do we split on?

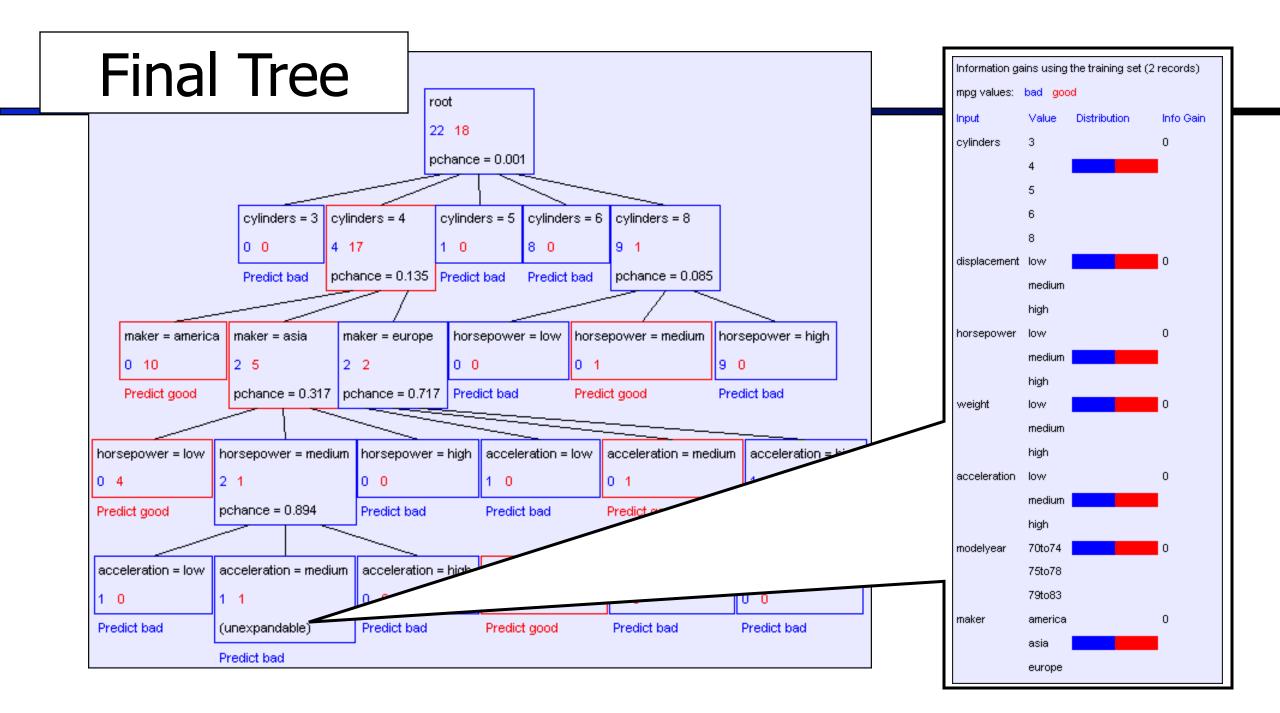

#### **Result: Decision Stump**

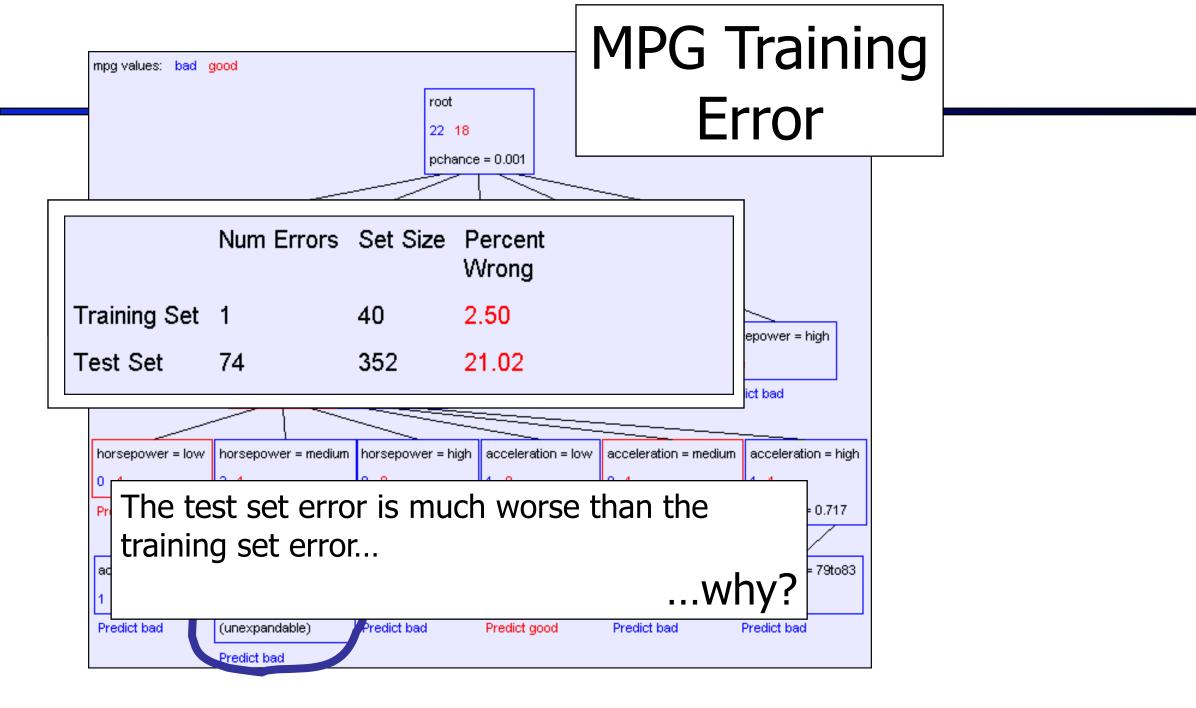

#### Second Level

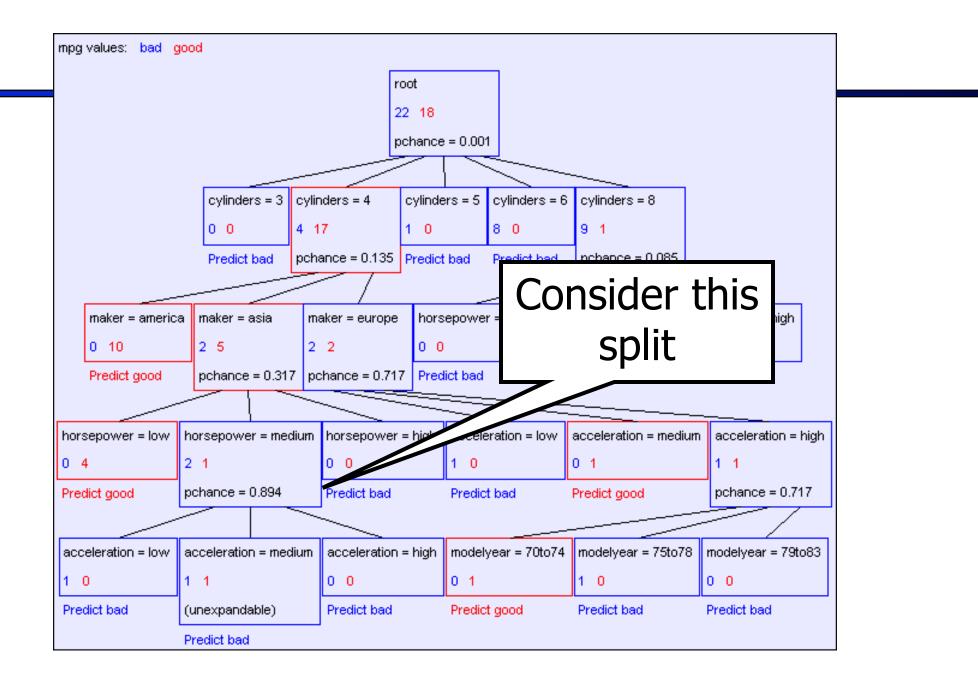

## **Reminder: Overfitting**

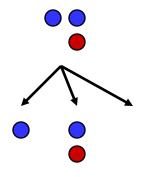

- Overfitting:
  - When you stop modeling the patterns in the training data (which generalize)
  - And start modeling the noise (which doesn't)
- We had this before:
  - Naïve Bayes: needed to smooth
  - Perceptron: early stopping

# Significance of a Split

- Starting with:
  - Three cars with 4 cylinders, from Asia, with medium HP
  - 2 bad MPG
  - 1 good MPG
- What do we expect from a three-way split?
  - Maybe each example in its own subset?
  - Maybe just what we saw in the last slide?
- Probably shouldn't split if the counts are so small they could be due to chance
- A chi-squared test can tell us how likely it is that deviations from a perfect split are due to chance\*
- Each split will have a significance value, p<sub>CHANCE</sub>

# **Keeping it General**

#### Pruning:

- Build the full decision tree
- Begin at the bottom of the tree
- Delete splits in which

#### $p_{CHANCE} > MaxP_{CHANCE}$

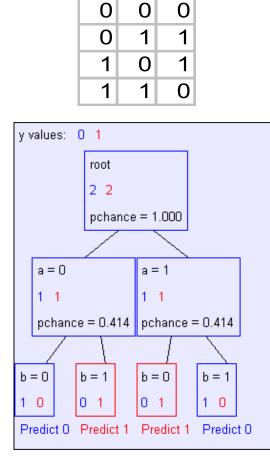

- Continue working upward until there are no more prunable nodes
- Note: some chance nodes may not get pruned because they were "redeemed" later

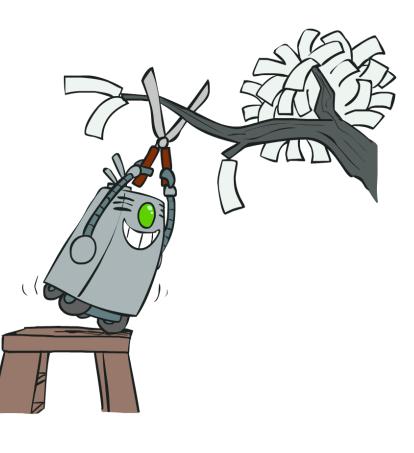

b

У

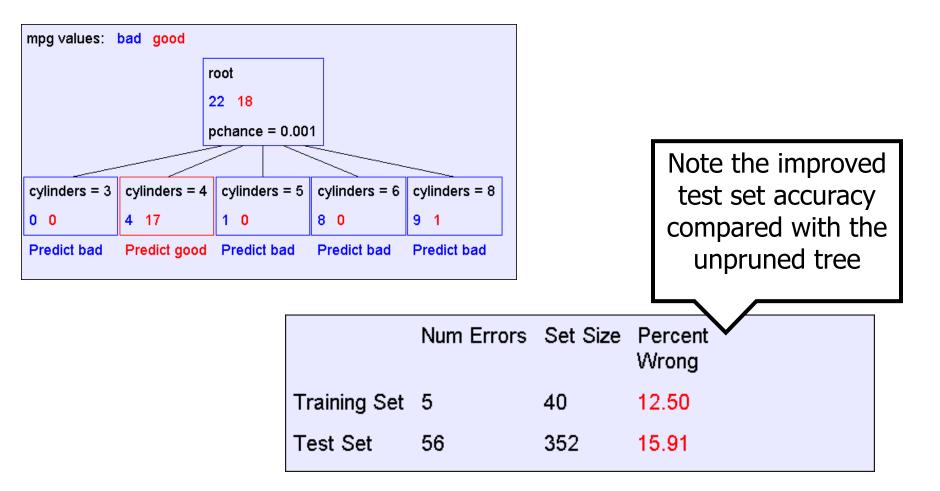

а

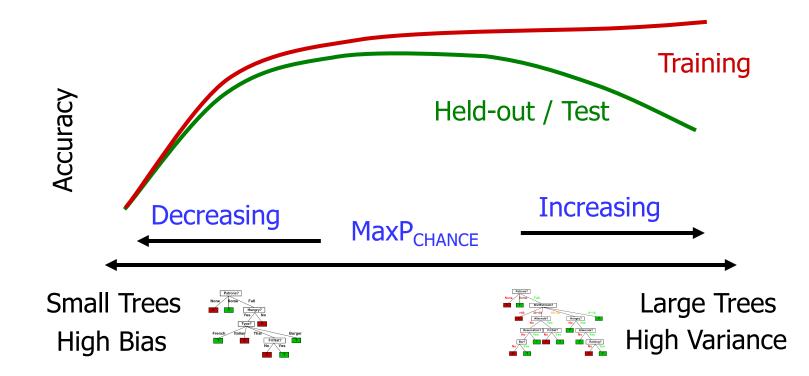

### Pruning example

• With MaxP<sub>CHANCE</sub> = 0.1:

## Regularization

- MaxP<sub>CHANCE</sub> is a regularization parameter
- Generally, set it using held-out data (as usual)

#### Two Ways of Controlling Overfitting

- Limit the hypothesis space
  - E.g. limit the max depth of trees
  - Easier to analyze
- Regularize the hypothesis selection
  - E.g. chance cutoff
  - Disprefer most of the hypotheses unless data is clear
  - Usually done in practice
